fracture gradient - Schlumberger Oilfield Glossary For example, a fracture gradient of 0.7 psi/ft [15.8 kPa/m] in a well with a true vertical depth of 8000 ft [2440 m] would predict a fracturing pressure of 5600 psi [38.6 MPa]. What is Fracture Gradient? - Definition from Petropedia Fracture gradient is the slope and pressure required in order to initiate a fracture or a crack into a rock formation. It is necessary to break into the arrangement of the rocks underground, so that conducive channels can be prepared for the oil and gas to flow easily. Hydraulic fracturing - Wikipedia The fracture gradient is defined as pressure increase per unit of depth relative to density, and is usually measured in pounds per square inch, per square foot, or bars. The rock cracks, and the fracture fluid permeates the rock extending the crack further, and further, and so on.

Fracture Gradient Prediction and Its Application in ... Overburden stress gradient, formation pore pressure gradient and Poisson's ratio of rocks were the independent variables that were shown to control fracture pressure gradient, the dependent variable. In 1967, Matthews and Kelly published another fracture pressure gradient equation that is different from that of Hubbert and Willis in that a variable "matrix stress coefficient" concept was utilized. Fracture Gradient definitions - Defined Term Fracture Gradient: The fracture gradient is a measure of how the pressure required to fracture rock in the earth changes with depth. It is usually measured in units of "pounds per square inch per foot" (psi/ft) and varies with the type of rock and the stress history of the rock. FORMATION FRACTURE GRADIENT - wildwell.com Formation Fracture pressure is the amount of pressure necessary to permanently split or break the rock structure of a formation. Just overcoming formation pressure is normally not enough to create a fracture.
